

Codon divergence depends on alignment choices

1,625 matched gene groups • full distributions and all cases retained

A Divergence sensitivity

B Alignment retention and divergence

0 = unchanged; +1 = doubled; -1 = halved. Tree-total dS/dN use the declared opportunity normalization.

One zero/zero global-omega case has no log ratio; it remains in the data export and panel B.

Descriptive sensitivity, not selection evidence. Coverage, alignment, topology and fitted parameters can all contribute.
